# THE SOLUBILITY OF $\mathrm{CO}_{2}$ AND $\mathrm{N}_{2} \mathrm{O}$ IN SOME $\mathrm{C}_{6}$ HYDROCARBONS AT HIGH PRESSURES 

## I. Găinar*

#### Abstract

In this study we have studied the solubility of $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$ in a series of $\mathrm{C}_{6}$ hydrocarbons, namely: n-hexane, cyclohexane and metyl-cyclopentane by pressure up to 35 bar and temperatures in a range of $0 \div 25^{\circ} \mathrm{C}$. In all investigated systems we have found remarkable values of gas solubility with specific features that evidence some effects depending of the structure of solvents. The regular solutions theory was employed as theoretical model for calculation the solubility of gases in the investigated solvents.

## Introduction

This work is a continuation of a programme initiated for some years ago concerning the solubility of gases in a wide category of organic solvents: hydrocarbons, alchols, ketones at high pressure and a wide domain of temperatures $[1 \div 3]$.

## Materials and Methods

The experimental device and the detailed description of working method is presented in a separate research [4]. By using of this experimental method we have performed a study concerning the influence of the isomeric effects on gas solubility. In this purpose we have selected two cyclic hydrocarbons namely cyclohexane and metyl-cyclopentane and two gases with likewise properties, $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$. As a reference we have select the solubility of these gases in n -hexane. The working domain was temperatures among $273.16 \div 298.16 \mathrm{~K}$ and pressures up to 50 bar. The finding of experimental data for the mentioned system is very difficult because in this temperature interval the vapour pressures of all solvents possess considerable values. Moreover, because the solubility are obtained by measurement the amount of disrobed gas after vacuum détente of gas saturated liquid was necessary to cool the gathering ampoule at $-20^{\circ} \mathrm{C}$ to condense the vapours of the solvent.

## Results and Discussion

The experimental values of gas solubility are presented in Table 1 for the systems solvents with $\mathrm{CO}_{2}$ and in Table 2 for the systems solvents with $\mathrm{N}_{2} \mathrm{O}$.

Table 1. Experimental values of gas solubility.

One can remark considerable values of gas solubility for all investigated systems. Concerning the absolute values of solubility's expressed as molar fractions one observe noteworthy features that spotlight the influence of structural effects on gas solubility.
The smaller values of solubility were observed for systems n-hexane $+\mathrm{CO}_{2}$ and n-hexane + $\mathrm{N}_{2} \mathrm{O}$. For all investigated temperatures and pressures the solubility of $\mathrm{CO}_{2}$ in n -hexane is considerable greater as for $\mathrm{N}_{2} \mathrm{O}$ in the same solvent.
For the other systems (cyclohexane and metyl-cyclopentane $+\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$ respectively) the solubility are much greater. For example, for the system metyl-cyclopentane $+\mathrm{CO}_{2}$ at temperature of 273.16 K the molar fraction of $\mathrm{CO}_{2}$ has a value of about 0.6 and in similar condition the solubility of $\mathrm{CO}_{2}$ in cyclohexane exceed the value 0.5 .

For the systems cyclohexane and metyl-cyclopentane $+\mathrm{N}_{2} \mathrm{O}$ the solubilities reach to values of 0.8 . This means the appearance of a new equilibrium: the solvent dissolved in the compressed gas, these increased values on the result of the interaction between the molecules of gas and those of the hydrocarbons.
For all investigated systems one observe at higher pressures and lower temperatures considerable deviation from Henry law. At 298.16 K the dependence $P=f\left(x_{2}{ }^{1}\right)$ is a straight line and therefore the Henry law is respected. A proof of this assertion is the fact that the values of solubility obtained by extrapolation at $\mathrm{P}=1 \mathrm{~atm}$ are $\left(\mathrm{x}_{2}\right)_{\mathrm{CO} 2}=0.41$ and $\left(\mathrm{x}_{2}\right)_{\mathrm{N} 2 \mathrm{O}}=0.40$.
A rigorous method for the prediction of gas solubility requires a valid theory of solution but such of theory is not available. For a semiempirical description of non-polar systems the theory of regular solution can serve as a basis for the correlation of gas solubility [ $5 \div 7$ ].

For that purpose to consider a gas dissolved isothermally in a liquid far from its critical temperature. The dissolution process is accompanied by a change in enthalpy and in entropy as in the case when two liquids are mixed. The dissolution of a gas in a liquid is accompanied by a large reduction in volume, since the volume of the solute in the condensed phase is much smaller then that in the gas phase. This large decrease in volume differentiates the dissolution of a gas from the dissolution of a liquid. In order to apply
regular solution theory which assess no volume change - it is necessary to condense firstly the gas up to a volume close to the partial molar volume of a solute dissolved in a certain solvent. The isothermal dissolution process is then considered in two steps:

$$
\begin{gather*}
\Delta G=\Delta G_{1}+\Delta G_{2}  \tag{1}\\
\Delta G_{1}=R T \ln f_{2}^{l} / f_{2}^{0}  \tag{2}\\
\Delta G_{2}=R T \ln \gamma_{2}^{l} \cdot x_{2}^{l} \tag{3}
\end{gather*}
$$

In the first step the gas is isothermally condensed up to a hypothetical state having a volume as a liquid. In the second step this hypothetical liquid is dissolved in the solvent. Since the solute from the liquid solution is in equilibrium with the gas at unit fugacity, the equation of equilibrium is:

$$
\begin{equation*}
\Delta G=0 \tag{4}
\end{equation*}
$$

The regular solution theory allows the calculation of the activity coefficient of the gaseous solute with the relation:

$$
\begin{equation*}
R T \ln \gamma_{2}^{l}=V_{2}^{l}\left(\delta_{1}-\delta_{2}\right)^{2} \cdot \phi_{1}^{2} \tag{5}
\end{equation*}
$$

The substitution of equations (1), (2) and (5) into equation (4) gives the solubility at 1 atm partial pressure:

$$
\begin{equation*}
\frac{1}{x_{2}^{l}}=\frac{f_{2}^{l}}{f_{2}^{0}} \exp \frac{V_{2}^{l} \cdot\left(\delta_{1}-\delta_{2}\right)^{2} \cdot \phi_{1}^{2}}{R T} \tag{6}
\end{equation*}
$$

This correlating scheme involves three parameters for the gaseous component as a hypothetical liquid: the fugacity, the volume and the solubility parameter. These parameters are all temperature dependent; however the theory the theory of regular solution assumes that at constant composition $\ln \gamma_{2}^{l}$ is proportional with $1 / T$ and therefore the quantity $V_{2}^{l} \cdot\left(\delta_{1}-\delta_{2}\right)^{2} \cdot \phi_{1}^{2}$ is not temperature dependent. Thus, any convenient temperature may be used to specify $V_{2}^{l}$ and $\delta_{2}$ provided the same temperature is used for $\delta_{1}$ and $V_{1}^{l}$. The most convenient temperature is $25^{\circ} \mathrm{C}$. The fugacity of the hypothetical liquid must be however treated as a function of temperature. The small effect of solvent on $V_{2}^{l}$ need not be considered for the purposes of this work because the volume change is much smaller than that corresponding to step 1.
The fugacity of the hypothetical liquid solute at a pressure of 1 atm depends only on the temperature and properties of the solute and is independent of the properties of the solvent. It is possible therefore to apply the theorem of corresponding states and to show that the reduced fugacity of the hypothetical liquid solute is a universal function of the reduced temperature. For the reduced temperature range 0.7 to 0.8 vapor-pressure data for liquefied gases (such as $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$ ) were used to obtain a plot of $f_{2}^{l} / P_{c}$ versus $T / T_{c}$ (Fig. 1) [8].

Fig. 1: Fugacity of a hypothetical liquid at partial pressure of 1 atm .
For the calculation that we performed at partial pressure of $1 \mathrm{~atm}\left(f_{2}^{l}=1\right)$, the molar fraction of the solute in the liquid phase is much smaller as unity and in this case we consider the volume fraction $\phi_{1}=1$.

The results obtained by application the regular solution model are presented in the Table 3.
Table 3. The calculated solubility of gases by application of the regular solution model.

| Gas | Solvent | $\delta_{1}$ <br> $\left({\left.\mathrm{cal} / \mathrm{cm}^{3}\right)^{1 / 2}}\right.$ | $\delta_{2}$ <br> $\left(\mathrm{cal} / \mathrm{cm}^{3}\right)^{1 / 2}$ | $\mathrm{V}_{2}{ }^{1}$ <br> $\left(\mathrm{~cm}^{3} / \mathrm{mol}\right)$ | $\mathrm{T}_{\mathrm{c}}$ <br> $(\mathrm{K})$ | $\mathrm{P}_{\mathrm{c}}$ <br> $(\mathrm{bar})$ | $\mathrm{f}_{2}{ }^{1}$ <br> $(\mathrm{bar})$ | $\mathrm{x}_{2}{ }^{1}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{CO}_{2}$ | n-hexane | 7.30 | 6.0 | 55 | 304.25 | 73 | 29.2 | 0.0292 |
| $\mathrm{CO}_{2}$ | cyclohexane | 8.20 | 6.0 | 55 | 304.25 | 73 | 29.2 | 0.0220 |
| $\mathrm{CO}_{2}$ | metyl-cyclopentane | 8.0 | 6.0 | 55 | 304.25 | 73 | 29.2 | 0.0240 |
| $\mathrm{~N}_{2} \mathrm{O}$ | n-hexane | 7.30 | 7.6 | 36 | 309.65 | 71.7 | 43.02 | 0.0230 |
| $\mathrm{~N}_{2} \mathrm{O}$ | cyclohexane | 8.20 | 7.6 | 36 | 309.65 | 71.7 | 43.02 | 0.0232 |
| $\mathrm{~N}_{2} \mathrm{O}$ | metyl-cyclopentane | 8.0 | 7.6 | 36 | 309.65 | 71.7 | 43.02 | 0.0227 |

The calculated values are in good concordance with those obtained by application the Henry law in the form $x_{2}^{l}=1 / f_{2}^{g}$.

## Conclusions

By using of a genuine experimental device one have determined the solubility of $\mathrm{CO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}$ in three non-polar solvents: n -hexane, cyclohexane and metyl-cyclopentane at pressure up to 50 bar and in the temperature domain of $273.16 \div 298.16 \mathrm{~K}$. We have found remarkable values for solubility of gases in all organic solvents with great deviation from Henry law, especially for low temperatures. For correlation of gas solubility we have applied the regular solution model.
